1) Load the 100 pairs of corresponding 2-D and 3-D points in the files 2Dpoints.txt and 3Dpoints.txt (the i^{th} row of both files corresponds to the i^{th} point). Use these point correspondences to solve (using Eigenanalysis) for the camera matrix P (whose rasterized vector \mathbf{p} has a unit L2 norm). [5 pts]

Camera matrix P:

```
P =
-0.0021 -0.0020 -0.0017 0.9123
0.0006 -0.0001 -0.0028 0.4094
-0.0000 0.0000 -0.0000 0.0007
```

2) Given the computed matrix P (from Problem 1), project the 3-D homogeneous points $(X_i, Y_i, Z_i, 1)$ to 2-D. Compute the sum-of-squared error (sum-of-squared distances) between the resulting 3-D-to-2-D projected points and the given 2-D points (ensure all 2-D points are inhomogeneous). [3 pts]

sum-of-squared error = 18.7461

3)The file homography.txt contains 15 corresponding 2-D points from two different images, where the first and second columns correspond to the x and y coordinates of the points in the first image and the third and fourth columns correspond to the x and y coordinates of the points in the second image. Load the 2-D point sets and use the **Normalized Direct Linear Transformation algorithm** to compute the final homography H that maps the original points *from* image 1 to image 2 (i.e., make sure P2 = HP1). [5 pts]

Final homography H:

H = 0.3875 0.4842 -21.3951 -0.0609 0.2709 90.4191 0.0003 0.0003 0.4072

4)Plot the points from image 2 and the projected points from image 1 on the same plot. Make sure the projected points are converted into inhomogeneous form. [1 pt]

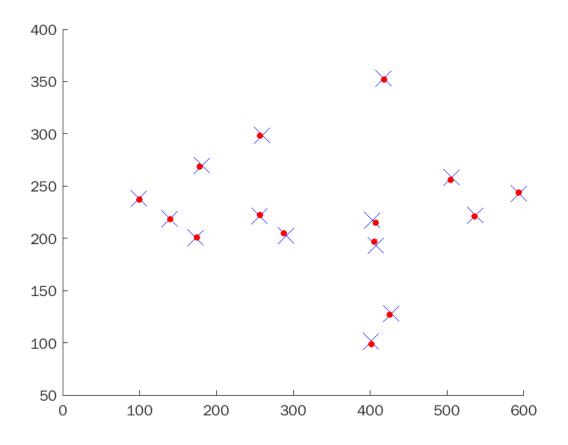

Image 1: Blue X

Image 2: Red dots

As we can see, points from image2 are very close to the corresponding projection points, which means our result is good.

5)Compute the sum-of-squared error (squared Euclidean distance) between the actual points from image 2 and the projected points from image 1. [2 pts]

sum-of-squared error = 105.9739

6)As usual, upload the standard material.

```
